**Abstract**—Industry 4.0 is a new industry trend which relies on data driven business model to set the productivity requirements of the cyber physical system. To meet this requirement, Industry 4.0 cyber physical systems need to be highly scalable, adaptive, real-time, and reliable. Recent successful industrial wireless standards such as WirelessHART appeared as a feasible approach for such cyber physical systems. For reliable and real-time communication in highly unreliable environments, they adopt a high degree of redundancy. While a high degree of redundancy is crucial to real-time control, it causes a huge waste of energy, bandwidth, and time under a centralized approach, and are therefore less suitable for scalability and handling network dynamics. To address these challenges, we propose DistributedHART - a distributed real-time scheduling system for WirelessHART networks. The essence of our approach is to adopt local (node-level) scheduling through a time window allocation among the nodes that allows each node to schedule its transmissions using a real-time scheduling policy locally and online. DistributedHART obviates the need of creating and disseminating a central global schedule in our approach, and thereby significantly reducing resource usage and enhancing the scalability. To our knowledge, it is the first distributed real-time multi-channel scheduler for WirelessHART. We have implemented DistributedHART and experimented on a 130-node testbed. Our tested experiments as well as simulations show at least 85% less energy consumption in DistributedHART compared to existing centralized approach while ensuring similar schedulability.

### I. INTRODUCTION

Industry 4.0 is a new industry trend which relies on a data-driven business model to set the productivity requirements of the cyber-physical systems. To meet these requirements, cyber-physical systems need to be highly scalable, adaptive, real-time and reliable. Recent successful industrial wireless standards such as WirelessHART have shown their feasibility as a cost-efficient, real-time, and robust approach for such cyber-physical systems [7]. To make reliable and real-time communication in highly unreliable wireless environments, WirelessHART adopts a high degree of redundancy using a Time Division Multiple Access (TDMA) based Media Access Control (MAC) protocol. A time slot can be either *dedicated* (i.e., a time slot when at most one transmission is scheduled to a receiver) or *shared* (i.e., a time slot when multiple nodes may contend to send to a common receiver). To handle transmission failures, each node on a path from a sensor to an actuator is assigned two dedicated time slots and a third shared slot on a separate path for another retransmission [2]. A network manager creates the

\*co-first author

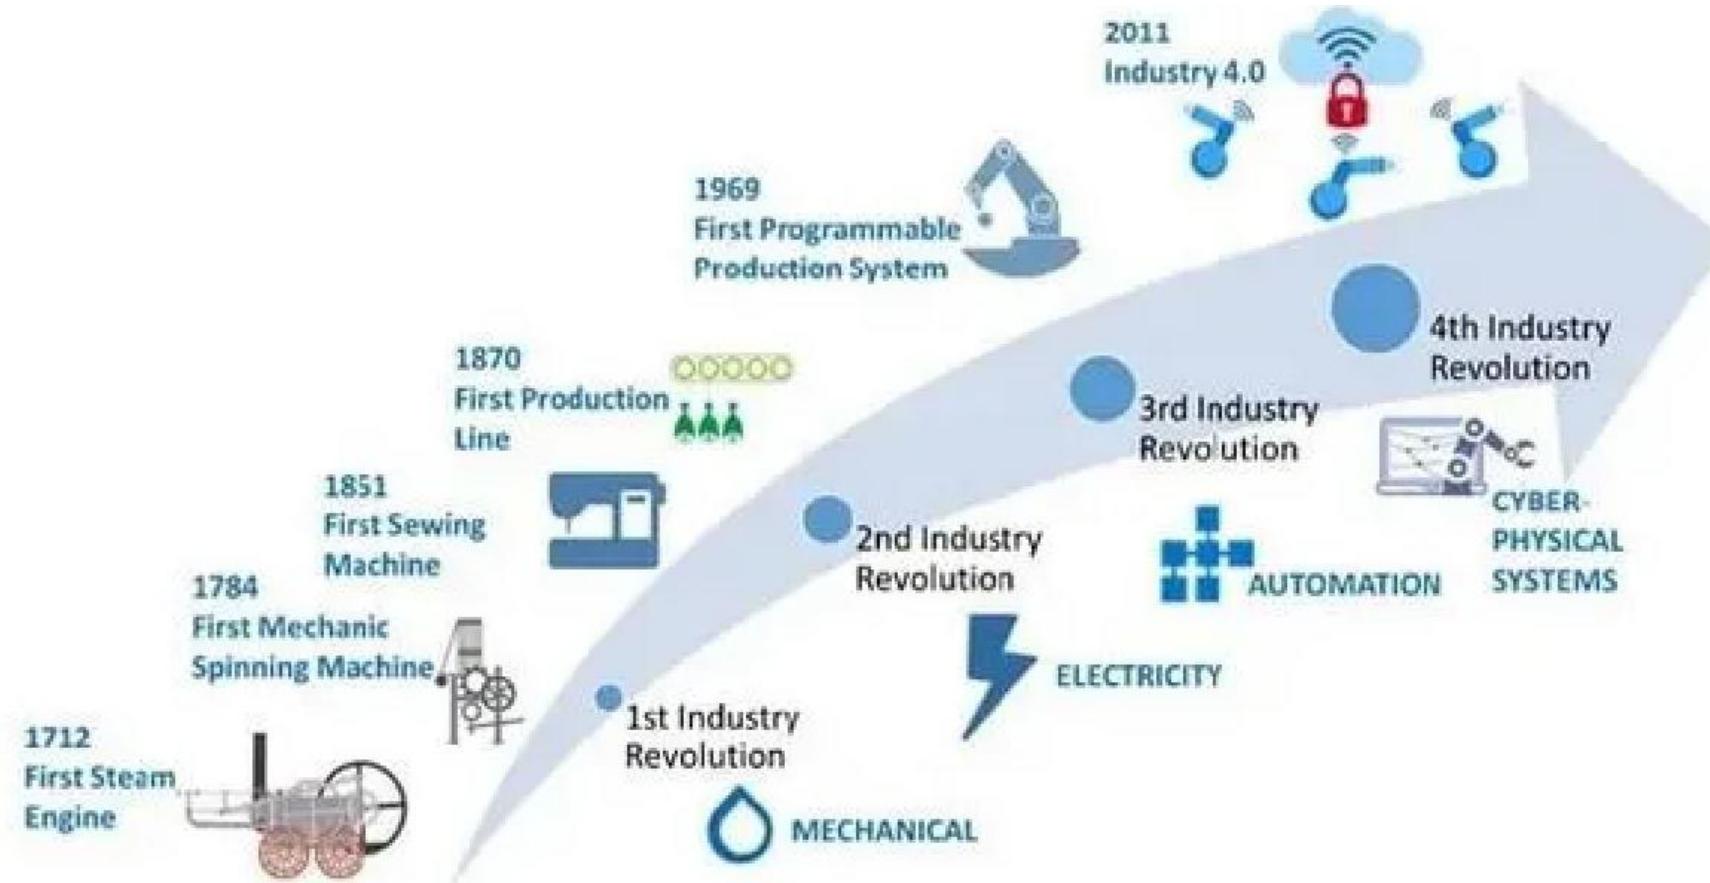

transmission schedule **centrally** and in advance for all nodes in the network and then disseminates them. A centralized WirelessHART scheduler with high redundancy raises several practical challenges in achieving scalability as described below.

High level of redundancy in centralized algorithms [27], [29] causes a huge waste of time and bandwidth, and hence is not scalable. For example, if the transmission of a packet along a particular link succeeds, all time slots (on the current link and redundant links) that were assigned to handle its failure remain unused. Similarly, if it fails along that particular link, all time slots that were assigned for its subsequent links to handle a successful transmission remain unused. Our experiments observed up to 70% unused time slots in WirelessHART networks (see Section IV). Furthermore, there can be events or emergencies that occur unpredictably or aperiodically. For example, a WirelessHART network in an oil-refinery may suddenly detect a safety valve displacement requiring immediate attention to avoid accidents. Existing solution handles emergencies by allocating time slots in the centrally created schedule and by stealing slots in the absence of emergencies [17]. However, this approach leaves most of the slots of the periodic server unstolen, and hence unused. Thus the network remains largely underutilized which affects the scalability of the system.

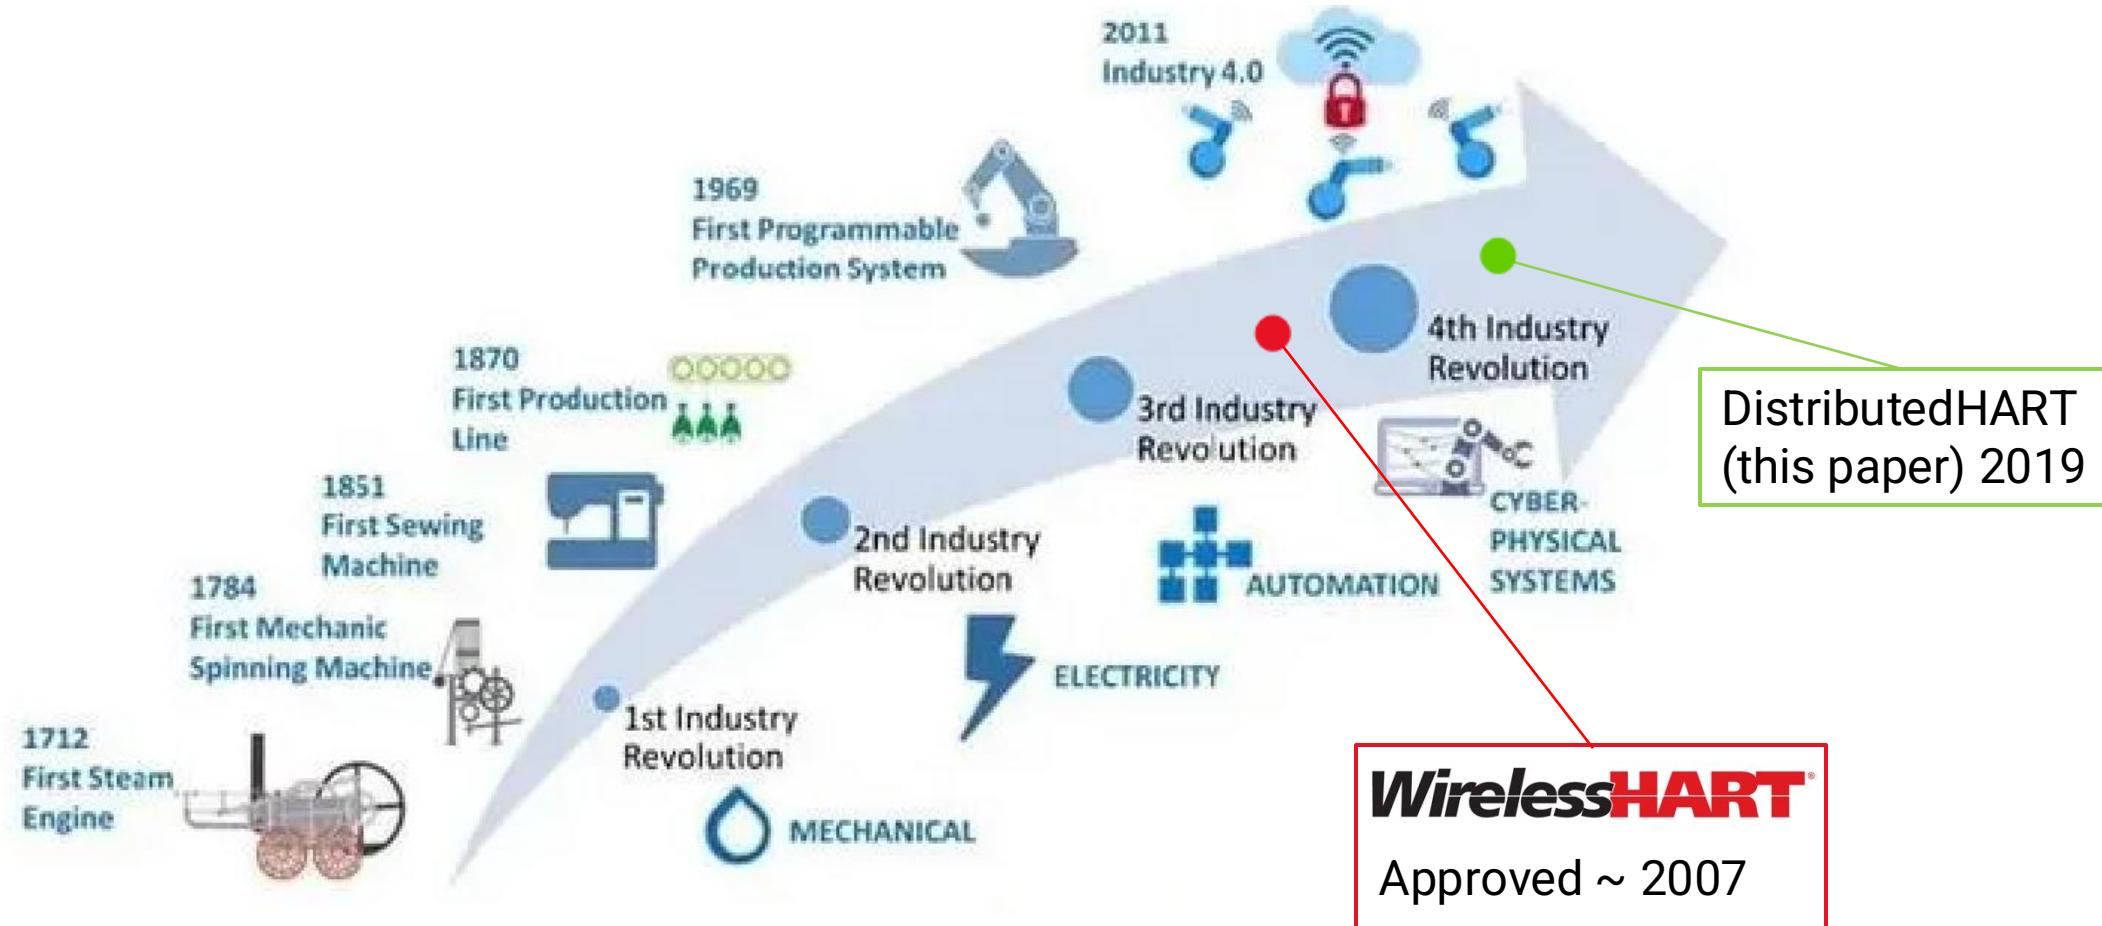

Schedules dissemination in centralized algorithm consumes bandwidth, energy, and time, even for a smaller network or a smaller workload. Typically, hyper-period and length of the schedule increase exponentially with the increase in the number of flows or their periods, which hinders the scalability of the network. Note that, in general, periods can be non-harmonic to ensure stability or control performance [28]. In Industry 4.0, the data-driven business model introduces frequent changes to sampling rates, which requires re-configuration and re-dissemination of schedules. In addition, network dynamics such as a change in channel, node, or link condition requires reconfiguration and re-dissemination of schedules [29]. Such frequent re-dissemination of the schedule consumes very high energy, time, and bandwidth. Thus, a fully centralized WirelessHART scheduling is less suitable for cyber-physical systems, especially those in the domain of Industry 4.0 [6]. Besides, it is typically suitable for deterministic traffic patterns such as periodic traffics or traffics with known arrival pattern.

To address the above limitations, in this paper, we propose a distributed real-time scheduling system for WirelessHART networks. Designing a distributed TDMA protocol with scheduling

# Industry 4.0

# Industry 4.0

# Motivation

---

## Address WirelessHART's limitations:

- Industry 4.0 suitability
- Network utilization
- Energy intensive

## Maintain Performance:

- Scalable
- Adaptive
- Reliable
- Real-time

# Limitation 1: High Level of Redundancy

## Multiple paths

- Exponential scalability
- Network Manager globally tracks

## Underutilization under periodic conditions

- Up to 70% unused slots [27]

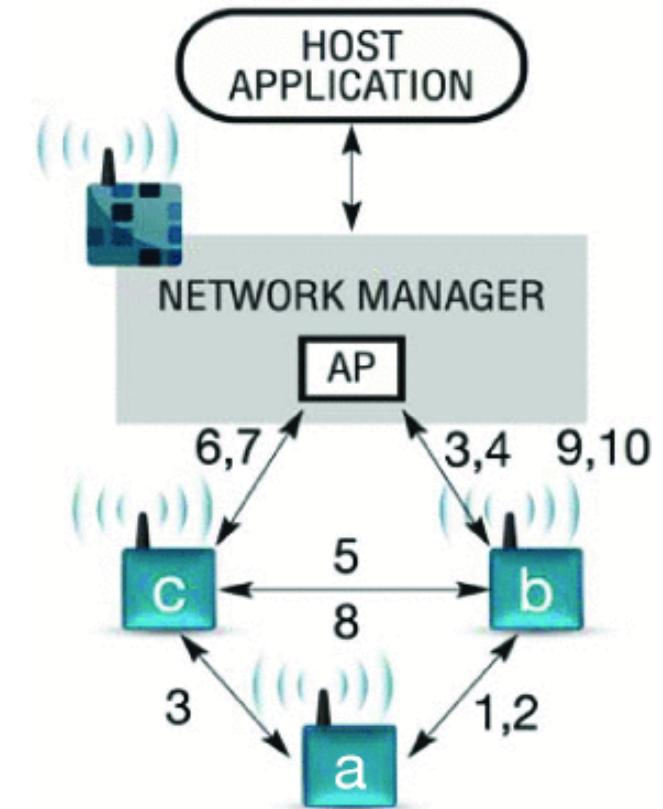

Figure 1: An example of scheduling in WirelessHART

# Limitation 2: Global Dissemination

## Exponential Growth with Number of Flows

- Hyper-period
- Schedule length

## Non-Adaptive

- Full re-dissemination
- High cost

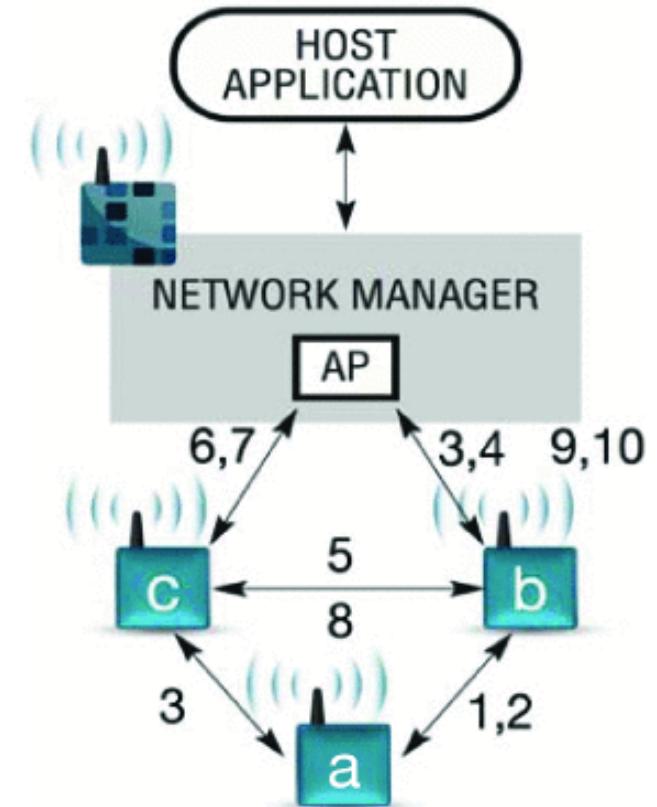

Figure 1: An example of scheduling in WirelessHART

# Proposed Architecture

---

## WirelessHART

- 802.15.4
- 16 channels
- TDMA MAC
- Multi-Hop
- Graph routing
- Scheduling performed by the Network Manager

## DistributedHART

- 802.15.4
- 16 channels
- TDMA MAC
- Multi-Hop
- With or without graph routing
- Scheduling performed locally by nodes, online

# Outcomes of Paper

---

1. Introduction of DistributedHART
2. Schedulability test to determine real-time performance with a high probability
3. Tests and simulations displaying DistributedHART's effectiveness

## Key Finding

- DistributedHART reduces energy consumption

# DistributedHART Design

# Design of DistributedHART

---

## Bulk of work done at node level

- Nodes schedule their transmissions locally online
- If first slot successful, nodes can use other windows to transmit

## Execution Order

1. Network Manager generates routes (global)
2. Channel Allocation (distributed, offline)
3. Time Window Allocation (distributed, online)
4. Real-Time Scheduling (local, online)

# Channel Allocation

---

## Signal-to-Noise plus Interference Ratio (SNIR)

- If SNIR exceeds threshold at radio, then two nodes in conflict

## \*Receiver conflict graph

- Each node maintains a physical interference model using SNIR
- Use vertex coloring to assign channels

## Outcome

- Channel conditions known; ability to handle network dynamics

# Time Window Allocation

---

## \*Transmitter conflict graph

- Graph over remaining conflicting nodes after channel allocation
- Two nodes have an edge if transmissions by both will lead to a collision at the recipients
- Use vertex coloring to assign time windows

## Outcome

- Nodes are aware of their neighbors and can save energy

# Epoch

---

## Epoch

- defines 1 full cycle of all assigned time windows, after which the sequence repeats.

**w:** time slots

**y:** total number of unique time windows

$$\text{epoch} = y \times w$$

**Goal:** minimize  $y$

**Assumption:** Each node has equal length  $w$

# Real-Time Scheduling

---

**Works on both fixed or dynamic policies**

- Deadline Monotonic (DM)
- Earliest Deadline First (EDF)

**Each node schedules autonomously**

- Each node knows priorities of packets at buffer
- Source nodes determine their sampling period/deadline

Nodes respond to aperiodic events **locally** without global dissemination

# DistributedHART EDF Scheduling Example

---

## Assumptions:

- only one channel
- Each node has equal length  $w$

**Nodes:** 5

**Flows:** 2

**Epoch:** 3

$$F = \{F_1, F_2\}$$

$$T_1 = 6$$

$$T_2 = 12$$

$$D_1 < D_2$$

# Slot Sharing

---

## Dedicated Slots

- time slots within a node's time window used immediately

## Shared Slots

- time slots within or outside a node's time window, used opportunistically if idle.

## If transmission failure is handled by nodes locally:

1. After failure, node waits for some  $\Theta$ .
2. After  $\Theta$ , If no transmissions sensed, take slot as “shared”.
3. wait random back-off and transmit packet.

$\Theta$ : sensing delay

# Slot Sharing Re-Transmission Example

2. After  $\theta$ , If no transmissions sensed, take slot as “shared”.
3. wait random back-off and transmit packet.

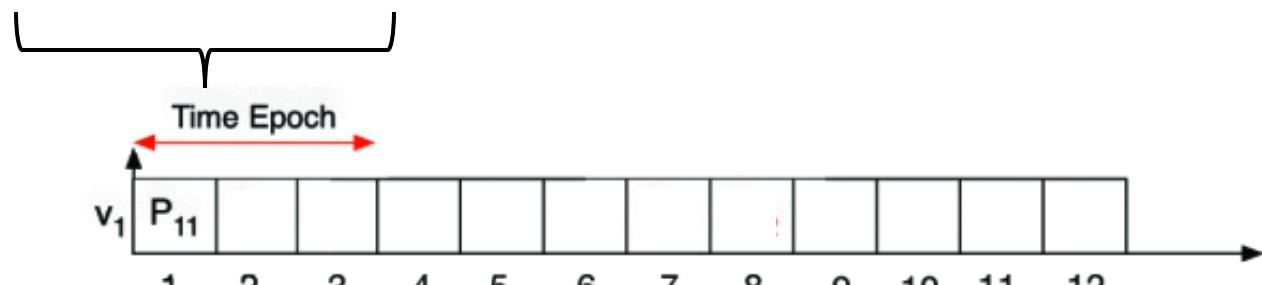

Figure 3: An example of scheduling as dedicated and shared slot

# Slot Sharing Re-Transmission Example

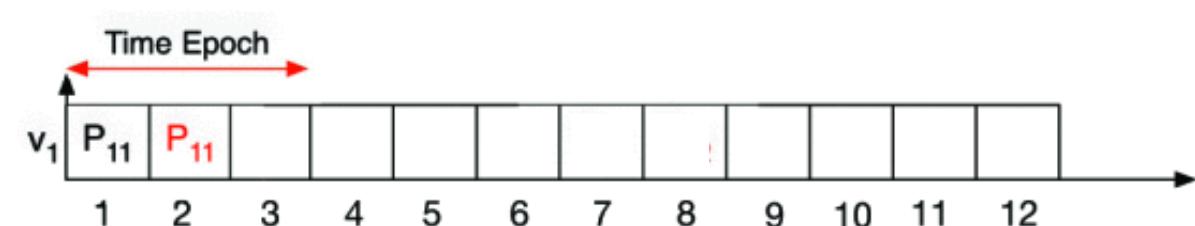

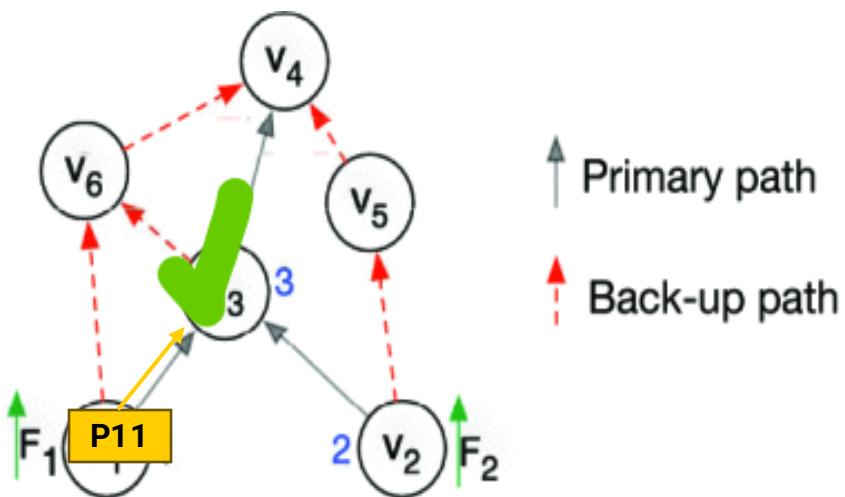

Figure 3: An example of scheduling as dedicated and shared slot

# Hidden Terminals

## Overlapping packet re-transmissions

- Two nodes cannot hear each other, and both transmit to a third node
- Failure in carrier sensing

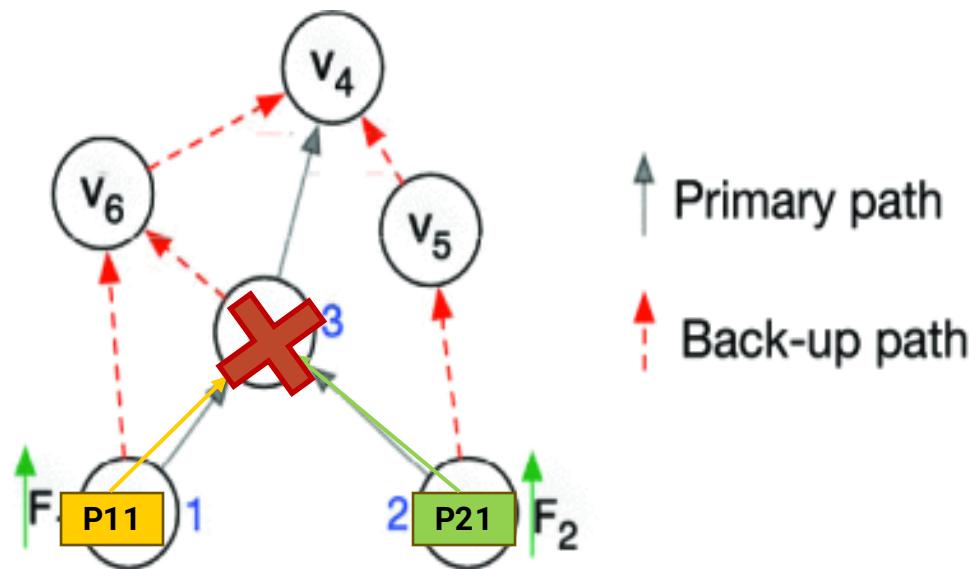

Figure 2a: Time window allocation example

# Capture Effect

---

## 802.15.4 Radio Behavior

1. Detect and locks preamble with strongest Received Signal Strength (RSS)
2. Once locked, raise interrupt, and stop searching
3. Decode packet and ignore subsequent packets

## Exploit

- If in dedicated slot, transmit at full power immediately
- If a re-transmission in shared slot, transmit at weaker power after  $\Theta$

# Capture Effect Experiment

## Setup

- 3 TesloB motes

## Goals

- Determine  $\Theta$  before re-transmission
- Determine re-transmission Tx power
- Observe distance variation

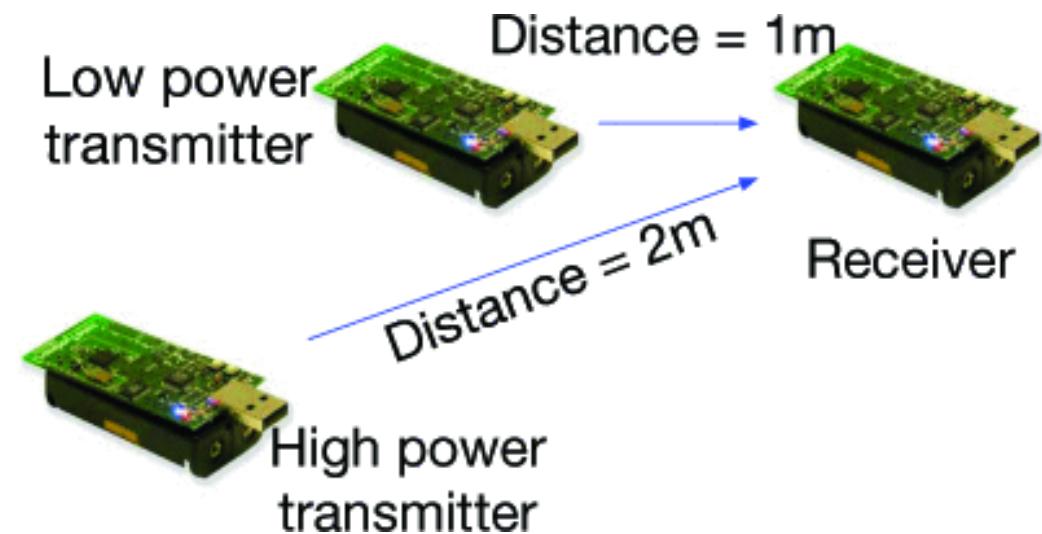

Figure 4: Capture effect experiment setup

## Metric

- Packet Reception Rate (PPR)

# Capture Effect Experiment

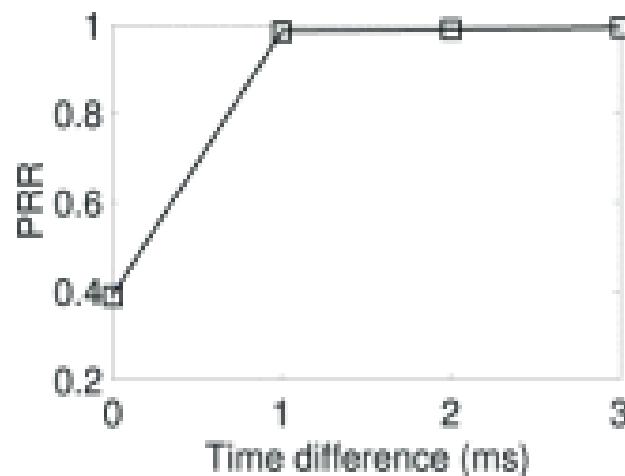

Figure 5a: Time difference

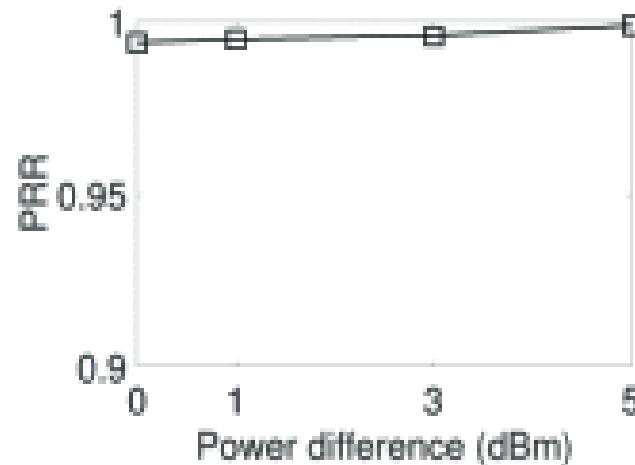

Figure 5b: Power difference

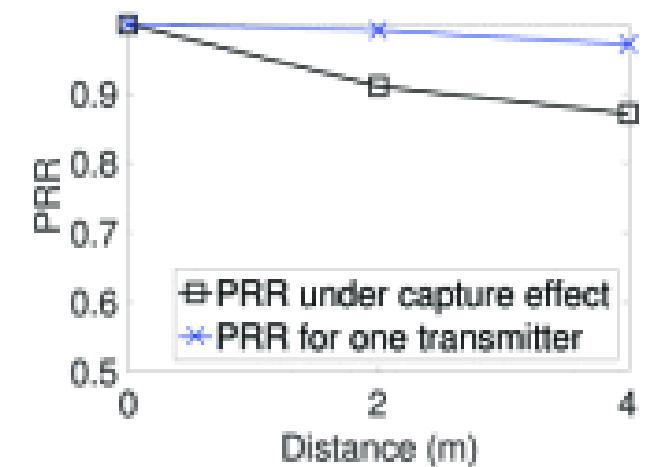

Figure 5c: Distance

## 5a Conditions

- Transmitters at 0dBm power
- Varied  $\theta$  between transmissions

## 5b Conditions

- Fixed  $\theta = 3$  ms.
- One transmitter kept at 0dBm, other reduced.

## 5c Conditions

- Fixed  $\theta = 3$  ms
- Fixed 3 dB power difference.
- Varied distance between transmitters and receiver.

# DistributedHART Analysis

(Probabilistic Worst Case)

# Flow Reception

---

$k$ : index representing a link

$E_i$ : set of links making up primary route of flow  $F$

$p_k$ : probability successful transmission over link  $k$

$$\mathbb{P}(F)_i = \prod_{k \in E_i} \left(1 - (1 - \rho_k)^2\right)$$

Equation 1: P(successful reception of packet through primary path of graph a route)

# Flow Delay

---

$V_j$  = set of nodes in primary path  $F_j$

$I_v(F_i) = \{ F_j \mid v \in V_j \}$  = set of flows passing through node  $v$

$$\delta_v(F_i) = (\gamma - 1) \times w + 2 + \sum_{F_j \in I_v(F_i)} \max \left\{ 0, 1 + \left\lfloor \frac{\delta_v(F_i) - D_j}{T_j} \right\rfloor \right\} 2 \times \gamma$$

Equation 2: total delay experience by a flow  $F_i$  at node  $v$

# Flow Delay

$V_j$  = set of nodes in primary path  $F_j$

$I_v(F_i) = \{ F_j \mid v \in V_j \}$  = set of flows passing through node  $v$

Links typically  
scheduled on 2 time slots

$$\delta_v(F_i) = (\gamma - 1) \times w + 2 + \sum_{F_j \in I_v(F_i)} \max \left\{ 0, 1 + \left\lfloor \frac{\delta_v(F_i) - D_j}{T_j} \right\rfloor \right\} 2 \times \gamma$$

# Test Results

# Testbed Setup

---

## Setup

- **Platform:** TinyOS 2.2 running TelosB motes
- **Network Size:** 130 nodes
- **Transmit Power:** -28.7 dBm
- **Topology:** 4-hop
- **Routing Baseline:** Centralized graph routing
- **Manager Role:** Computed initial channel and time-window allocations centrally
- **Scheduling Policies:** EDF and DM (with spatial reuse)
- **Energy Estimation:**
  - USBs used for power, use product of # transmissions x energy consumed
  - 5.5ms Tx time, 0.22mg consumed per communication

## Metrics

1. **Energy:** energy consumed per node (J)
2. **Memory:** memory consumed to store a schedule (KB)
3. **Convergence Time:** average time taken for all nodes to obtain a schedule (s)
4. **Schedulability Ratio:** fraction of test cases schedulable among all cases

# Simulation Results

# Simulation Setup

---

## Setup

- **Simulator:** TOSSIM (TinyOS Simulator)
- **Network Size:** 148 nodes
- **Transmit Power:** -28.7 dBm
- **Fully-Distributed:** channel and time window allocated by nodes (both initially and operationally)
- **Test-Cases:**
  - 50 randomly selected sensor/actuators
  - Sensor/Actuators assigned random harmonic periods in the range of  $2^{11-13}$  time slots
  - Every 10 flows, double the range
- **Scheduling Policies:** WirelessHART/DistributedHART EDF and DM, Orchestra, DiGS

## Metrics

1. **Energy:** energy consumed per node (J)
2. **Memory:** memory consumed to store a schedule
3. **Convergence Time:** average time taken for all nodes to obtain a schedule
4. **Schedulability Ratio:** fraction of test cases schedulable among all cases

# Conclusion

---

## DistributedHART

- More suitable for Industry 4.0
- Higher network utilization
- 85% less energy intensive

## Performance

- Highly scalable
- Improved adaptability
- Preserves reliability
- Questionable latency
- Decreased Schedulability in small networks
